#### Abstract

We give a new expression for the expected number of inversions in the product of $n$ random adjacent transpositions in the symmetric group $\mathfrak{S}_{m+1}$. We then derive from this expression the asymptotic behaviour of this number when $n \equiv n_{m}$ scales with $m$ in various ways. Our starting point is an equivalence, due to Eriksson et al., with a problem of weighted walks confined to a triangular area of the plane.

Keywords: Permutations, Markov chains, Inversions

## 1 Introduction

Let $\mathfrak{S}_{m+1}$ denote the group of permutations on the set $\{0,1,2, \ldots, m\}$. Define the adjacent transposition $s_{i}$ to be the two-cycle $(i, i+1)$. We consider the adjacent transposition Markov chain $\pi^{(0)}, \pi^{(1)}, \pi^{(2)}, \ldots$ on $\mathfrak{S}_{m+1}$. That is, $\pi^{(0)}$ is the identity, and $\pi^{(n+1)}=\pi^{(n)} s_{i}$, where $i \in\{0, \ldots, m-1\}$ is chosen uniformly at random. For instance, denoting $\pi=\pi_{0} \pi_{1} \cdots \pi_{m}$ if $\pi(i)=\pi_{i}$ for all $i$, we may have, when $m=3$,

$$
\begin{aligned}
& \pi^{(0)}=0123=\mathrm{id} \\
& \pi^{(1)}=0213=\pi^{(0)} s_{1} \\
& \pi^{(2)}=2013=\pi^{(1)} s_{0} \\
& \pi^{(3)}=2103=\pi^{(2)} s_{1}
\end{aligned}
$$

Markov chains on finite groups have attracted a lot of interest in, at least, the past 30 years, at the interface of algebra and probability theory [1, 11, 14, 15, 26, 27]. Such chains are also studied in computational biology, in connection with models of gene mutations [3, 16, 19, 20, 29]. A central question is to estimate the mixing time of the chain, for large values of $m$. (The mixing time is the number of steps the chain takes to approach its equilibrium distribution.) The above chain is periodic of period 2, since $\pi^{(2 n)}$ is always in the alternating group. Thus it has no equilibrium distribution. However, an elementary modification (which consists in choosing $\tilde{\pi}^{(n+1)}=\tilde{\pi}^{(n)}$ with probability $1 /(m+1)$ and otherwise multiplying by a transposition $s_{i}$ chosen uniformly) makes it aperiodic, and the equilibrium distribution is then uniform over $\mathfrak{S}_{m+1}$. The mixing time is known to be $\Theta\left(m^{3} \log m\right)$ (see Aldous [1], Diaconis and Saloff-Coste [14] and Wilson [30]).

More recently, Berestycki and Durrett [4] studied a continuous time version of this chain, denoted $\left(X_{t}^{m}\right)_{t \geq 0}$, where multiplications by adjacent transpositions occur according to a Poisson process of rate 1. The connection with the chain $\pi^{(n)}$ described above is straightforward. The authors focussed on the inversion number $D_{t}^{m}$ of $X_{t}^{m}$, as a function of $m$ and $t$. They established the convergence in probability of this random variable, suitably normalized, when $t \equiv t_{m}$ scales with $m$ in various ways. The limit is usually described in probabilistic terms, except in one simple regime, $m \ll t \ll m^{3}$, where $D_{t}^{m} / \sqrt{m t}$ is shown to converge to $\sqrt{2 / \pi}$. Of course, the interesting regimes are those occurring before stationarity.

This paper actually stems from a remark made in Berestycki \& Durrett's paper. They quote a paper by Eriksen [18], which gives a rather formidable expression for $\mathrm{I}_{m, n}$, the expected number of inversions in $\pi^{(n)}$ :

$$
\begin{equation*}
\mathrm{I}_{m, n}=\sum_{r=1}^{n} \frac{1}{m^{r}}\binom{n}{r} \sum_{s=1}^{r}\binom{r-1}{s-1}(-4)^{r-s} g_{s, m} h_{s, m} \tag{1}
\end{equation*}
$$

with

$$
g_{s, m}=\sum_{\ell=0}^{m} \sum_{k \geq 0}(-1)^{k}(m-2 \ell)\binom{2\lceil s / 2\rceil-1}{\lceil s / 2\rceil+\ell+k(m+1)}
$$

and

$$
h_{s, m}=\sum_{j \in \mathbb{Z}}(-1)^{j}\binom{2\lfloor s / 2\rfloor}{\lfloor s / 2\rfloor+j(m+1)}
$$

The authors underline that "it is far from obvious how to extract useful asymptotic from this formula". This observation motivated our interest in the expectation $\mathrm{I}_{m, n}$. As the problem is of an algebraic nature, it should have much structure: would it be possible to find an alternative expression of $\mathrm{I}_{m, n}$, with a neater structure than (1), and to derive asymptotic results from this expression?

This is precisely what we do in this paper. Our alternative formula for $\mathrm{I}_{m, n}$ reads as follows.
Theorem 1 Let $m \geq 1$. For $k \in \mathbb{Z}$, denote

$$
\begin{equation*}
\alpha_{k}=\frac{(2 k+1) \pi}{2 m+2}, \quad c_{k}=\cos \alpha_{k}, \quad s_{k}=\sin \alpha_{k} \quad \text { and } \quad x_{j k}=1-\frac{4}{m}\left(1-c_{j} c_{k}\right) \tag{2}
\end{equation*}
$$

The expected number of inversions after $n$ adjacent transpositions in $\mathfrak{S}_{m+1}$ is

$$
\mathrm{I}_{m, n}=\frac{m(m+1)}{4}-\frac{1}{8(m+1)^{2}} \sum_{k, j=0}^{m} \frac{\left(c_{j}+c_{k}\right)^{2}}{s_{j}^{2} s_{k}^{2}} x_{j k}{ }^{n} .
$$

Equivalently, the generating function $\mathrm{I}_{m}(t)=\sum_{n \geq 0} \mathrm{I}_{m, n} t^{n}$ is

$$
\begin{equation*}
\mathrm{I}_{m}(t)=\frac{m(m+1)}{4(1-t)}-\frac{1}{8(m+1)^{2}} \sum_{k, j=0}^{m} \frac{\left(c_{j}+c_{k}\right)^{2}}{s_{j}^{2} s_{k}^{2}} \frac{1}{1-t x_{j k}} \tag{3}
\end{equation*}
$$

This result is proved in Section 2, and asymptotic results are derived in Sections 3 to 5 for three main regimes: linear $\left(n_{m}=\Theta(m)\right.$ ) and before, cubic $\left(n_{m}=\Theta\left(m^{3}\right)\right.$ ) and beyond, intermediate ( $m \ll n_{m} \ll$ $\left.m^{3}\right)$. For the moment, let us give a few comments and variants on Theorem 1 .

Limit behaviour. The chain $\pi^{(n)}$ has period 2, as $\pi^{(n)}$ is an even (resp. odd) permutation if $n$ is even (resp. odd). But the sub-chains $\pi^{(2 n)}$ and $\pi^{(2 n+1)}$ are aperiodic on their respective state spaces, the alternating group $\mathfrak{A}_{m+1}$ (the group of even permutations) for $\pi^{(2 n)}$ and its complement $\mathfrak{S}_{m+1} \backslash \mathfrak{A}_{m+1}$ for $\pi^{(2 n+1)}$. Moreover, each of these chains is irreducible and symmetric, and thus admits the uniform distribution as its equilibrium distribution. For $m \geq 3$, the average number of inversions of an element of $\mathfrak{A}_{m+1}$ is $m(m+1) / 4$, and the same is true of elements of $\mathfrak{S}_{m+1} \backslash \mathfrak{A}_{m+1}$. Thus when $m \geq 3$ is fixed and $n \rightarrow \infty$, we expect $\mathrm{I}_{m, n}$ to tend to $m(m+1) / 4$. This can be seen on the above expression of $\mathrm{I}_{m, n}$, upon observing that, for $m \geq 3$ and $0 \leq j, k \leq m$ with $j+k \neq m$, there holds $x_{j k} \in(-1,1)$. (The condition $j+k \neq m$ is equivalent to $c_{j}+c_{k} \neq 0$.) If $m \geq 8$, the stronger property $x_{j k} \in(0,1)$ holds, which shows that $\mathrm{I}_{m, n}$ is an increasing function of $n$.

Eigenvalues of the transition matrix. Another consequence of the above theorem is that we have identified a quadratic number of eigenvalues of the transition matrix of the chain (see [18] for a detailed account of the connection between these eigenvalues and $\mathrm{I}_{m, n}$ ).

Corollary 2 Let $c_{k}=\cos \frac{(2 k+1) \pi}{2 m+2}$. The transition matrix of the adjacent transposition Markov chain on $\mathfrak{S}_{m+1}$ admits -among others- the following eigenvalues:

$$
x_{j k}=1-\frac{4}{m}\left(1-c_{j} c_{k}\right),
$$

for $0 \leq j, k \leq m$ and $j+k \neq m$.

This result is not really new: as pointed to us by David Wilson, one can derive from the proof of Lemma 9 in [30] that for $0 \leq p, q \leq m$, with $p \neq q$,

$$
1-\frac{2}{m}\left(2-\cos \frac{p \pi}{m+1}-\cos \frac{q \pi}{m+1}\right)
$$

is also an eigenvalue. This collection is larger than the one we have exhibited, as can be seen using

$$
2 c_{j} c_{k}=\cos \frac{(k-j) \pi}{m+1}+\cos \frac{(k+j+1) \pi}{m+1}
$$

The transition matrix has still more eigenvalues, for instance -1 , with eigenvector $(\varepsilon(\sigma))_{\sigma \in \mathfrak{S}_{m+1}}$ where $\varepsilon$ denotes the signature. The paper [17], originally motivated by a coding problem, gives a linear number of eigenvalues of the form $i / m$, where $i$ is an integer. There exists a description of all eigenvalues in terms of the characters of $\mathfrak{S}_{m+1}$ (see [15, Thm. 3]). This description is valid in a much more general framework, and it seems that the complete list of eigenvalues is not explicitly known.

Rationality of $\mathrm{I}_{m}(t)$. That the series $\mathrm{I}_{m}(t)$ is always rational should not be a surprise: this property is
clear when considering the transition matrix of the chain. Here are the first few values:

$$
\begin{aligned}
\mathrm{I}_{1}(t) & =\frac{t}{(1-t)(1+t)} \\
\mathrm{I}_{2}(t) & =\frac{t(2+t)}{(1-t)(2-t)(1+t)} \\
\mathrm{I}_{3}(t) & =\frac{3 t\left(27+9 t-7 t^{2}-t^{3}\right)}{(1-t)\left(9+6 t-t^{2}\right)\left(9-6 t-t^{2}\right)} \\
\mathrm{I}_{4}(t) & =\frac{t\left(256-192 t-48 t^{2}+44 t^{3}-5 t^{4}\right)}{(1-t)\left(16-5 t^{2}\right)\left(16-20 t+5 t^{2}\right)}
\end{aligned}
$$

A related aperiodic chain. If we consider instead the aperiodic variant of the chain (obtained by choosing $\tilde{\pi}^{(n+1)}=\tilde{\pi}^{(n)}$ with probability $1 /(m+1)$ and otherwise multiplying by a transposition $s_{i}$ chosen uniformly), it is easy to see that the expected number of inversions after $n$ steps is now

$$
\tilde{\mathbf{I}}_{m, n}=\sum_{k=0}^{n}\binom{n}{k} \frac{m^{k}}{(m+1)^{n}} \mathbf{I}_{m, k}
$$

so that the associated generating function is also rational:

$$
\tilde{\mathrm{I}}_{m}(t):=\sum_{n \geq 0} \tilde{\mathrm{I}}_{m, n} t^{n}=\frac{1}{1-t /(m+1)} \mathrm{I}_{m}\left(\frac{t m}{m+1-t}\right)
$$

More generally, if a transposition occurs with probability $p$, the generating function of the expected number of inversions is

$$
\frac{1}{1-t(1-p)} \mathrm{I}_{m}\left(\frac{t p}{1-t(1-p)}\right)
$$

(Above, $p=m /(m+1)$, but in [30] for instance, $p=1 / 2$.)
Alternative expressions. Theorem 1 gives a partial fraction expansion of $I_{m}(t)$. One of the advantages of (3) is that the coefficients involved in the sum over $j$ and $k$ are negative, which makes the list of poles of $I_{m}(t)$ clear (we have actually already used this to state Corollary 2 . A number of variations are possible, and we will use some of them in the asymptotic study of the numbers $\mathrm{I}_{m, n}$. For instance:

$$
\begin{align*}
\mathrm{I}_{m}(t) & =\frac{m(m+1)}{4(1-t)}-\frac{1}{8(m+1)^{2}} \sum_{k, j=0}^{m} \frac{c_{j}+c_{k}}{\left(1-c_{j}\right)\left(1-c_{k}\right)} \frac{1}{1-t x_{j k}}  \tag{4}\\
& =\frac{1}{8(m+1)^{2}} \sum_{k, j=0}^{m} \frac{c_{j}+c_{k}}{\left(1-c_{j}\right)\left(1-c_{k}\right)}\left(\frac{1}{1-t}-\frac{1}{1-t x_{j k}}\right) \tag{5}
\end{align*}
$$

Both formulas are proved in Section 2

## 2 The expected number of inversions

We prove in this section Theorem 1 and its variants (4/5). Our starting point is a functional equation satisfied by a series related to $I_{m}(t)$. We then solve this equation using the bivariate kernel method, which has proved successful in the past few years in various enumerative problems related to lattice paths, permutations, and other combinatorial objects [7, 8, 9, 10, 23, 25, 31]. The equation under consideration here can be interpreted in terms of weighted lattice paths confined to a triangular portion of the square lattice. Another problem of walks in a triangle, also related to the adjacent transposition Markov chain, was studied by Wilson [30] via a diagonalization of the adjacency matrix. The enumeration of (unweighted) walks in a triangle was performed by Flajolet [21] using the reflection principle, in connection with a problem of storage raised by Knuth [24, Ex. 2.2.2.13].

### 2.1 A functional equation

For $\pi \in \mathfrak{S}_{m+1}$, let us write $\pi=\pi_{0} \pi_{1} \cdots \pi_{m}$ if $\pi(i)=\pi_{i}$ for all $i$. For $n \geq 0$ and $0 \leq i \leq j<m$, let

$$
p_{i, j}^{(n)}=\mathbb{P}\left(\pi_{i}^{(n)}>\pi_{j+1}^{(n)}\right)
$$

Then the expected number of inversions in $\pi^{(n)}$ is

$$
\begin{equation*}
\mathrm{I}_{m, n}=\sum_{0 \leq i \leq j<m} p_{i, j}^{(n)} \tag{6}
\end{equation*}
$$

Examining how the numbers $p_{i, j}^{(\cdot)}$ may change at the $n^{\text {th }}$ step gives a recurrence relation for these numbers, first obtained by Eriksson et al. [20]. As shown by the lemma below, it converts our problem into the study of weighted walks confined to a triangular region of the square lattice. Consider the subgraph $G_{m}$ of the square lattice $\mathbb{Z} \times \mathbb{Z}$ induced by the points $(i, j)$, with $0 \leq i \leq j<m$ (Figure 1 ). We use the notation $(i, j) \leftrightarrow(k, \ell)$ to mean that the points $(i, j)$ and $(k, \ell)$ are adjacent in this graph.

Fig. 1: The graph $G_{m}$.

Lemma 3 ([20]) The inversion probabilities $p_{i, j}^{(n)}$ are characterized by the following recursion:

$$
p_{i, j}^{(0)}=0 \quad \text { for } \quad 0 \leq i \leq j<m
$$

and for $n \geq 0$,

$$
p_{i, j}^{(n+1)}=p_{i, j}^{(n)}+\frac{1}{m} \sum_{(k, \ell) \leftrightarrow(i, j)}\left(p_{k, \ell}^{(n)}-p_{i, j}^{(n)}\right)+\frac{\delta_{i, j}}{m}\left(1-2 p_{i, j}^{(n)}\right)
$$

where $\delta_{i, j}=1$ if $i=j$ and 0 otherwise.
As often, it is convenient to handle the numbers $p_{i, j}^{(n)}$ via their generating function:

$$
P(t ; u, v) \equiv P(u, v):=\sum_{n \geq 0} t^{n} \sum_{0 \leq i \leq j<m} p_{i, j}^{(n)} u^{i} v^{j}
$$

Multiplying the above recursion by $t^{n+1}$, and then summing over $n$, gives the following functional equation for $P(u, v)$.

Corollary 4 The series $P(u, v)$ satisfies

$$
\begin{align*}
& \left(1-t+\frac{t}{m}(4-u-\bar{u}-v-\bar{v})\right) P(u, v)= \\
& \quad \frac{t}{m}\left(\frac{1-u^{m} v^{m}}{(1-u v)(1-t)}-(\bar{u}-1) P_{\ell}(v)-(v-1) v^{m-1} P_{t}(u)-(u+\bar{v}) P_{d}(u v)\right) \tag{7}
\end{align*}
$$

where $\bar{u}=1 / u, \bar{v}=1 / v$, and the series $P_{\ell}, P_{t}$ and $P_{d}$ describe the numbers $p_{i, j}^{(n)}$ on the three borders (left, top, and diagonal) of the graph $G_{m}$ :

$$
\begin{align*}
& P_{\ell}(v)=\sum_{n \geq 0} t^{n} \sum_{0 \leq j<m} p_{0, j}^{(n)} v^{j} \\
& P_{t}(u)=\sum_{n \geq 0} t^{n} \sum_{0 \leq i<m} p_{i, m-1}^{(n)} u^{i} \\
& P_{d}(u)=\sum_{n \geq 0} t^{n} \sum_{0 \leq i<m} p_{i, i}^{(n)} u^{i} . \tag{8}
\end{align*}
$$

In view of (6), the generating function we are interested in is

$$
\mathrm{I}_{m}(t)=\sum_{n \geq 0} \mathrm{I}_{m, n} t^{n}=P(1,1)
$$

which, according to the functional equation (7), may be rewritten

$$
\begin{equation*}
\mathrm{I}_{m}(t)=\frac{t}{(1-t)^{2}}-\frac{2 t P_{d}(1)}{m(1-t)} \tag{9}
\end{equation*}
$$

In the next subsection, we solve (7), at least to the point where we obtain a closed form expression of $P_{d}(1)$, and hence a closed form expression of $\mathrm{I}_{m}(t)$, as announced in Theorem 1 .

### 2.2 Solution of the functional equation

We first establish a symmetry property of the series $P(u, v)$.
Lemma 5 The series $P(u, v)$ satisfies

$$
P(u, v)=u^{m-1} v^{m-1} P(\bar{v}, \bar{u})
$$

with $\bar{u}=1 / u, \bar{v}=1 / v$. In particular, the "diagonal" generating function $P_{d}(u)$ satisfies

$$
\begin{equation*}
P_{d}(u)=u^{m-1} P_{d}(\bar{u}) \tag{10}
\end{equation*}
$$

Proof: This can be derived from the functional equation satisfied by $P(u, v)$, but we prefer to give a combinatorial (or probabilistic) argument.
Let $\tau$ be the permutation of $\mathfrak{S}_{m+1}$ that sends $k$ to $m-k$ for all $k$. Note that $\tau$ is an involution. Let $\Phi$ denote the conjugacy by $\tau$ : that is, $\Phi(\sigma)=\tau \sigma \tau$. Of course, $\Phi(\mathrm{id})=\mathrm{id}$ and $\Phi\left(\sigma \sigma^{\prime}\right)=\Phi(\sigma) \Phi\left(\sigma^{\prime}\right)$. Also, $\Phi$ has a simple description in terms of the diagram of $\sigma$, in which $\sigma(i)$ is plotted against $i$ : the diagram of $\Phi(\sigma)$ is obtained by applying a rotation of 180 degrees to the diagram of $\sigma$. In particular, with $s_{i}=(i, i+1)$, one has $\Phi\left(s_{i}\right)=s_{m-1-i}$ for $0 \leq i<m$. These properties imply that the sequence of random permutations $\left(\Phi\left(\pi^{(0)}\right), \Phi\left(\pi^{(1)}\right), \Phi\left(\pi^{(2)}\right), \ldots\right.$ ) follows the same law as the original Markov chain $\left(\pi^{(0)}, \pi^{(1)}, \pi^{(2)}, \ldots\right)$. In particular, for $0 \leq i \leq j<m$,

$$
p_{i, j}^{(n)}=\mathbb{P}\left(\Phi\left(\pi^{(n)}\right)_{i}>\Phi\left(\pi^{(n)}\right)_{j+1}\right)=\mathbb{P}\left(\pi_{m-j-1}^{(n)}>\pi_{m-i}^{(n)}\right)=p_{m-j-1, m-i-1}^{(n)} .
$$

This is equivalent to the first statement of the lemma. The second follows by specialization.
The next ingredient in our solution is the "obstinate" kernel method of [7, 8, 9, 10, 23, 25, 31]. The kernel of the functional equation (7) is the coefficient of $P(u, v)$, namely

$$
K(u, v)=1-t+\frac{t}{m}(4-u-\bar{u}-v-\bar{v})
$$

Let $(U, V)$ be a pair of Laurent series in $t$ that cancel the kernel: $K(U, V)=0$. The series $P(U, V)$ is well-defined (because $P(u, v)$ is a polynomial in $u$ and $v$ ). Setting $u=U$ and $v=V$ in (7) cancels the left-hand side, and thus the right-hand side. That is, denoting as usually $\bar{U}=1 / U$ and $\bar{V}=1 / V$,

$$
\frac{\bar{V}^{m-1}\left(1-U^{m} V^{m}\right)}{(1-U V)(\bar{U}-1)(V-1)(1-t)}-\frac{\bar{V}^{m-1} P_{\ell}(V)}{V-1}-\frac{P_{t}(U)}{\bar{U}-1}-\frac{\bar{V}^{m-1}(U+\bar{V})}{(\bar{U}-1)(V-1)} P_{d}(U V)=0
$$

provided $U \neq 1$ and $V \neq 1$. Let us now exploit the symmetries of the kernel: obviously, $K(u, v)$ is invariant by the transformations $u \mapsto \bar{u}$ and $v \mapsto \bar{v}$. Hence the pairs $(\bar{U}, V),(\bar{U}, \bar{V})$ and $(U, \bar{V})$ also cancel $K$, and it follows that

$$
\begin{aligned}
& \frac{\bar{V}^{m-1}\left(1-\bar{U}^{m} V^{m}\right)}{(1-\bar{U} V)(U-1)(V-1)(1-t)}-\frac{\bar{V}^{m-1} P_{\ell}(V)}{V-1}-\frac{P_{t}(\bar{U})}{U-1}-\frac{\bar{V}^{m-1}(\bar{U}+\bar{V})}{(U-1)(V-1)} P_{d}(\bar{U} V)=0 \\
& \frac{V^{m-1}\left(1-\bar{U}^{m} \bar{V}^{m}\right)}{(1-\bar{U} \bar{V})(U-1)(\bar{V}-1)(1-t)}-\frac{V^{m-1} P_{\ell}(\bar{V})}{\bar{V}-1}-\frac{P_{t}(\bar{U})}{U-1}-\frac{V^{m-1}(\bar{U}+V)}{(U-1)(\bar{V}-1)} P_{d}(\bar{U} \bar{V})=0
\end{aligned}
$$

$$
\frac{V^{m-1}\left(1-U^{m} \bar{V}^{m}\right)}{(1-U \bar{V})(\bar{U}-1)(\bar{V}-1)(1-t)}-\frac{V^{m-1} P_{\ell}(\bar{V})}{\bar{V}-1}-\frac{P_{t}(U)}{\bar{U}-1}-\frac{V^{m-1}(U+V)}{(\bar{U}-1)(\bar{V}-1)} P_{d}(U \bar{V})=0
$$

Let us form the alternating sum of the four previous equations: all occurrences of $P_{\ell}$ and $P_{t}$ vanish, and, using 10, one obtains, after multiplying by $U^{m} V^{m}(1-U)(1-V)$ :

$$
\begin{align*}
& (U V+1)\left(U^{m+1}+V^{m+1}\right) P_{d}(U V)+V^{m-1}(U+V)\left(1+U^{m+1} V^{m+1}\right) P_{d}(U \bar{V}) \\
& =\frac{U V}{1-t}\left(\frac{\left(1-U^{m} V^{m}\right)\left(U^{m}+V^{m}\right)}{1-U V}-\frac{\left(U^{m}-V^{m}\right)\left(1+U^{m} V^{m}\right)}{V-U}\right) \tag{11}
\end{align*}
$$

as soon as $K(U, V)=0, U \neq 1$ and $V \neq 1$.
This equation involves only one unknown series, namely $P_{d}$. So far, the series $U$ and $V$ are coupled by a single condition, $K(U, V)=0$. Let $q$ be a complex root of $q^{m+1}=-1$, and let us add a second constraint on the pair $(U, V)$ by requiring that $U=q V$. That is, $V$ must be a root of

$$
\begin{equation*}
K(q V, V)=1-t+\frac{t}{m}(4-(1+q)(V+\bar{q} \bar{V}))=0 \tag{12}
\end{equation*}
$$

where $\bar{q}=1 / q$ and $\bar{V}=1 / V$. We further assume $q \neq-1$ (otherwise $K(q v, v)$ is independent of $v$ ). Then $V \neq 1, U=q V \neq 1$, and the first term of (11) vanishes. We thus obtain an explicit expression of $P_{d}(q)$, which we write below in terms of $V$ and its conjugate root $V^{\prime}=\bar{q} \bar{V}$.

Lemma 6 Let $q \neq-1$ satisfy $q^{m+1}=-1$, and let $V \equiv V(t)$ and $V^{\prime} \equiv V^{\prime}(t)$ be the two roots of 12.). Then $V V^{\prime}=\bar{q}=1 / q$ and

$$
P_{d}(q)=\frac{\bar{q}}{(1-t)\left(V^{m+1}+V^{\prime m+1}\right)}\left(\frac{V^{m}+V^{\prime m}}{1-q}+\frac{1-\bar{q}}{1+q} \frac{V^{m}-V^{\prime m}}{V-V^{\prime}}\right)
$$

The series $V$ and $V^{\prime}$ are algebraic (of degree 2) over $\mathbb{C}(t)$. But their symmetric functions are rational, and thus $P_{d}(q)$ is rational too, as expected. The following lemma gives an explicit rational expression of $P_{d}(q)$.

Lemma 7 Let $q \neq-1$ satisfy $q^{m+1}=-1$. Assume $q=q_{k}:=e^{i \frac{2 k+1}{m+1} \pi}$. Then

$$
P_{d}\left(q_{k}\right)=\frac{2 i t}{q_{k}(1-t) m(m+1) s_{k}} \sum_{j=0}^{m} \frac{\left(c_{k}+c_{j}\right)\left(1-c_{k} c_{j}\right)}{1-t x_{j k}}
$$

with

$$
c_{j}=\cos \frac{(2 j+1) \pi}{2 m+2}, \quad s_{j}=\sin \frac{(2 j+1) \pi}{2 m+2} \quad \text { and } \quad x_{j k}=1-\frac{4}{m}\left(1-c_{j} c_{k}\right)
$$

## Equivalently,

$$
P_{d}\left(q_{k}\right)=\frac{i c_{k}}{2 q_{k}(1-t) s_{k}}-\frac{i}{2 q_{k}(m+1) s_{k}} \sum_{j=0}^{m} \frac{c_{k}+c_{j}}{1-t x_{j k}} .
$$

Proof: We will establish a closed form expression for the coefficient of $t^{n}$ in $(1-t) P_{d}(q)$, which is clearly equivalent to the first expression of $P_{d}(q)$ given above: for $n \geq 1$,

$$
\begin{align*}
a_{n} & :=\left[t^{n}\right](1-t) P_{d}(q) \\
& =\frac{2 i}{q m(m+1) s_{k}} \sum_{j=0}^{m}\left(c_{k}+c_{j}\right)\left(1-c_{k} c_{j}\right) x_{j k}^{n-1} \tag{13}
\end{align*}
$$

In order to obtain this expression, we begin with applying Cauchy's formula to the expression of $(1-$ $t) P_{d}(q)$ given in Lemma 6 Let $V$ be the root of 12 that vanishes at $t=0$. (The other root $V^{\prime}=\bar{q} \bar{V}$ has a term in $O(1 / t)$ in its expansion.) Then

$$
a_{n}=\frac{1}{2 i \pi} \int_{\circlearrowleft} R(V) \frac{d t}{t^{n+1}}
$$

where the integral is taken along a small circle around the origin, in counterclockwise direction,

$$
R(v)=\frac{\bar{q}}{v^{m+1}+(\bar{q} \bar{v})^{m+1}}\left(\frac{v^{m}+(\bar{q} \bar{v})^{m}}{1-q}+\frac{1-\bar{q}}{1+q} \frac{v^{m}-(\bar{q} \bar{v})^{m}}{v-\bar{q} \bar{v}}\right)
$$

and $\bar{v}=1 / v$. Obviously, $R(v)=R(\bar{q} \bar{v})$. By (12),

$$
\frac{1}{t}=1-\frac{4}{m}+\frac{1+q}{m}(V+\bar{q} \bar{V})
$$

so that

$$
\frac{d t}{t^{2}}=-\frac{1+q}{m}(V-\bar{q} \bar{V}) \frac{d V}{V}
$$

Thus the integral expression of $a_{n}$ reads

$$
a_{n}=\frac{1}{2 i \pi} \int_{\circlearrowleft} S(v) \frac{d v}{v}
$$

where the integral is taken along a small circle around the origin, in counterclockwise direction, and

$$
S(v)=-\frac{1+q}{m}(v-\bar{q} \bar{v})\left(1-\frac{4}{m}+\frac{1+q}{m}(v+\bar{q} \bar{v})\right)^{n-1} R(v)
$$

satisfies $S(\bar{q} \bar{v})=-S(v)$. Note that the only possible poles of $S(v) / v$ are 0 and the $(2 m+2)$ th roots of unity (because $q^{m+1}=-1$ ). Thus $a_{n}$ is simply the residue of $S(v) / v$ at $v=0$. Performing the change of variables $v=\bar{q} \bar{w}$, with $\bar{w}=1 / w$, gives

$$
a_{n}=\frac{1}{2 i \pi} \int_{\circlearrowright} S(w) \frac{d w}{w}
$$

where the integral is now taken along a large circle around the origin, in clockwise direction. This integral thus collects (up to a sign) all residues of $S(v) / v$. The residue formula thus gives:

$$
\begin{align*}
2 a_{n} & =\frac{1}{2 i \pi} \int_{\circlearrowright} S(w) \frac{d w}{w}+\frac{1}{2 i \pi} \int_{\circlearrowleft} S(v) \frac{d v}{v} \\
& =-\sum_{v^{2 m+2}=1} \frac{1}{v} \operatorname{Res}_{v}(S) \\
& =\frac{1}{2 m+2} \sum_{v^{2 m+2}=1} P(v) \tag{14}
\end{align*}
$$

where

$$
\begin{aligned}
& P(w)=\left(1-w^{2 m+2}\right) S(w)= \\
& \frac{1+\bar{q}}{m} w^{m+1}(w-\bar{q} \bar{w})\left(\frac{w^{m}+(\bar{q} \bar{w})^{m}}{1-q}+\frac{1-\bar{q}}{1+q} \frac{w^{m}-(\bar{q} \bar{w})^{m}}{w-\bar{q} \bar{w}}\right)\left(1-\frac{4}{m}+\frac{1+q}{m}(w+\bar{q} \bar{w})\right)^{n-1}
\end{aligned}
$$

Take $v=e^{i \alpha}$ with $\alpha=\ell \pi /(m+1)$ and $0 \leq \ell<2 m+2$ and recall that $q=e^{i \theta}$ with $\theta=\frac{(2 k+1) \pi}{m+1}$. Then

$$
\begin{aligned}
1+\bar{q} & =2 e^{-i \theta / 2} \cos (\theta / 2) \\
1-q & =-2 i e^{i \theta / 2} \sin (\theta / 2) \\
1-\bar{q} & =2 i e^{-i \theta / 2} \sin (\theta / 2) \\
1+q & =2 e^{i \theta / 2} \cos (\theta / 2) \\
v^{m+1} & =(-1)^{\ell} \\
v-\bar{q} \bar{v} & =2 i e^{-i \theta / 2} \sin (\alpha+\theta / 2) \\
v+\bar{q} \bar{v} & =2 e^{-i \theta / 2} \cos (\alpha+\theta / 2) \\
v^{m}+(\bar{q} \bar{v})^{m} & =2 i(-1)^{\ell+1} e^{i \theta / 2} \sin (\alpha+\theta / 2) \\
v^{m}-(\bar{q} \bar{v})^{m} & =2(-1)^{\ell} e^{i \theta / 2} \cos (\alpha+\theta / 2)
\end{aligned}
$$

Putting these identities together, one obtains

$$
\begin{aligned}
P(v)=\frac{4 i}{q m \sin (\theta / 2)}\left(\cos (\theta / 2) \sin ^{2}(\alpha+\theta / 2)+\right. & \left.\sin ^{2}(\theta / 2) \cos (\alpha+\theta / 2)\right) \\
& \times\left(1-\frac{4}{m}+\frac{4}{m} \cos (\theta / 2) \cos (\alpha+\theta / 2)\right)^{n-1}
\end{aligned}
$$

or, with the notation of the lemma,

$$
P(v)=\frac{4 i}{q m s_{k}}\left(c_{j}+c_{k}\right)\left(1-c_{j} c_{k}\right) x_{j k}^{n-1}
$$

with $j=k+\ell$. Returning to (14) now gives

$$
a_{n}=\frac{i}{q m(m+1) s_{k}} \sum_{j=-m-1}^{m}\left(c_{k}+c_{j}\right)\left(1-c_{k} c_{j}\right) x_{j k}^{n-1}
$$

which is equivalent to (13), upon noting that $c_{j}=c_{-j-1}$. The first expression of $P_{d}(q)$ given in the lemma follows.

For the second expression, we simply perform a partial fraction expansion in the variable $t$, based on

$$
\begin{equation*}
\frac{t}{(1-t)(1-x t)}=\frac{1}{1-x}\left(\frac{1}{1-t}-\frac{1}{1-x t}\right) \tag{15}
\end{equation*}
$$

and use

$$
\sum_{j=0}^{m} c_{j}=0
$$

(this identity follows for instance from $c_{m-j}=-c_{j}$ ).
Recall that $P_{d}(u)$ is a polynomial in $u$ of degree $m-1$. The above lemma gives its values at $m$, or even $m+1$, distinct points. Thus $P_{d}(u)$ is completely determined by these values, and we can recover it by interpolation. We use a version of Lagrange's interpolation that is well-suited to symmetric polynomials.

Lemma 8 Let $P(u)$ be a polynomial of degree $m-1$ with coefficients in some field containing $\mathbb{C}$. Assume $P(u)$ is symmetric. That is, $P(u)=u^{m-1} P(\bar{u})$, with $\bar{u}=1 / u$. Let $\ell=\left\lfloor\frac{m-1}{2}\right\rfloor$, and let $q_{0}, \ldots, q_{\ell}$ be distinct elements of $\mathbb{C}$ such that $q_{j} q_{k} \neq 1$ for all $k$ and $j$. Then

$$
\begin{equation*}
P(u)=(1+u)^{\chi_{m, 0}} \sum_{k=0}^{\ell} \frac{P\left(q_{k}\right)}{\left(1+q_{k}\right)^{\chi_{m, 0}}} \prod_{j \neq k} \frac{\left(u-q_{j}\right)\left(u-1 / q_{j}\right)}{\left(q_{k}-q_{j}\right)\left(q_{k}-1 / q_{j}\right)}, \tag{16}
\end{equation*}
$$

where $\chi_{m, 0}=1$ if $m$ is even, and 0 otherwise.
When $q_{k}=e^{i \theta_{k}}$ with $\theta_{k}=\frac{(2 k+1) \pi}{m+1}$, this can be rewritten as

$$
P(u)=-\frac{2 i}{m+1}\left(u^{m+1}+1\right) \sum_{k=0}^{\ell} P\left(q_{k}\right) \frac{q_{k} \sin \theta_{k}}{u^{2}-2 u \cos \theta_{k}+1} .
$$

In particular, with the notation (2),

$$
P(1)=-\frac{2 i}{m+1} \sum_{k=0}^{\ell} P\left(q_{k}\right) \frac{q_{k} c_{k}}{s_{k}}
$$

Proof: For the first part, it suffices to observe that the expression given on the right-hand side of (16) has degree $m-1$, and takes the same values as $P(u)$ at the $2 \ell+2$ distinct points $q_{0}, \ldots, q_{\ell}, 1 / q_{0}, \ldots, 1 / q_{\ell}$, and also at -1 if $m$ is even. This gives a total of $m+1$ correct values, which is more than enough to determine a polynomial of degree $m-1$.

For the second part, we observe that $q_{0}, \ldots, q_{\ell}, 1 / q_{0}, \ldots, 1 / q_{\ell}$, together with -1 if $m$ is even, are the $m+1$ roots of $u^{m+1}+1$. Hence

$$
(1+u)^{\chi_{m, 0}} \prod_{j \neq k}\left(u-q_{j}\right)\left(u-1 / q_{j}\right)=\frac{u^{m+1}+1}{\left(u-q_{k}\right)\left(u-1 / q_{k}\right)}
$$

which, in the limit $u \rightarrow q_{k}$, gives

$$
\left(1+q_{k}\right)^{\chi_{m, 0}} \prod_{j \neq k}\left(q_{k}-q_{j}\right)\left(q_{k}-1 / q_{j}\right)=-\frac{m+1}{q_{k}\left(q_{k}-1 / q_{k}\right)}
$$

The second result follows. The third one is obtained by setting $u=1$, and noticing that $\sin \theta_{k}=2 c_{k} s_{k}$, while $1-\cos \theta_{k}=2 s_{k}^{2}$.
We can finally combine this interpolation formula with Lemma 7 to obtain an explicit expression of $P_{d}(u)$. As we are mostly interested in $P_{d}(1)$ (see 9p), we give only this value.
Proposition 9 Let $\ell=\left\lfloor\frac{m-1}{2}\right\rfloor$, and adopt the notation (2). Then the series $P_{d}(u)$ defined by (8) satisfies:

$$
\begin{aligned}
P_{d}(1) & =\frac{m}{2(1-t)}-\frac{1}{(m+1)^{2}} \sum_{k=0}^{\ell} \sum_{j=0}^{m} \frac{c_{k}}{s_{k}^{2}} \frac{c_{j}+c_{k}}{1-t x_{j k}} \\
& =\frac{m}{2(1-t)}-\frac{1}{4(m+1)^{2}} \sum_{k=0}^{m} \sum_{j=0}^{m} \frac{\left(c_{j}+c_{k}\right)^{2}\left(1-c_{j} c_{k}\right)}{s_{j}^{2} s_{k}^{2}} \frac{1}{1-t x_{j k}}
\end{aligned}
$$

Proof: We apply Lemma 8 to the second expression of $P_{d}\left(q_{k}\right)$ obtained in Lemma 7 . This gives the first expression of $P_{d}(1)$ above, provided

$$
\begin{equation*}
\sum_{k=0}^{\ell} \frac{c_{k}^{2}}{s_{k}^{2}}=\frac{m(m+1)}{2} \tag{17}
\end{equation*}
$$

The latter identity is obtained by applying Lemma 8 to $P(u)=1+u+\cdots+u^{m-1}=\left(1-u^{m}\right) /(1-u)$.
We now seek a symmetric formula in $j$ and $k$. Using $c_{m-j}=-c_{j}, c_{m-k}=-c_{k}, s_{m-k}=s_{k}$ and $x_{j, k}=x_{m-j, m-k}$, we write

$$
\begin{aligned}
\sum_{k=0}^{\ell} \sum_{j=0}^{m} \frac{c_{k}}{s_{k}^{2}} \frac{c_{j}+c_{k}}{1-t x_{j k}} & =\sum_{k=0}^{\ell} \sum_{j=0}^{m} \frac{c_{m-k}}{s_{m-k}^{2}} \frac{c_{m-j}+c_{m-k}}{1-t x_{m-j, m-k}} \\
& =\sum_{k=m-\ell}^{m} \sum_{j=0}^{m} \frac{c_{k}}{s_{k}^{2}} \frac{c_{j}+c_{k}}{1-t x_{j k}} \\
& =\frac{1}{2} \sum_{k=0}^{m} \sum_{j=0}^{m} \frac{c_{k}}{s_{k}^{2}} \frac{c_{j}+c_{k}}{1-t x_{j k}} \\
& =\frac{1}{4} \sum_{k=0}^{m} \sum_{j=0}^{m}\left(\frac{c_{k}}{s_{k}^{2}}+\frac{c_{j}}{s_{j}^{2}}\right) \frac{c_{j}+c_{k}}{1-t x_{j k}}
\end{aligned}
$$

and this gives the second expression of $P_{d}(1)$.
Proof of Theorem 1: Let us now return to the generating function $I_{m}(t)$ whose coefficients give the expected number of inversions. It is related to $P_{d}(1)$ by $\sqrt{9}$. Theorem 1 is obtained by combining the
second expression of Proposition 9, a partial fraction expansion in $t$ (based on (15), and finally the identity

$$
\begin{equation*}
\sum_{j, k=0}^{m} \frac{\left(c_{j}+c_{k}\right)^{2}}{s_{j}^{2} s_{k}^{2}}=2 m(m+1)^{3} \tag{18}
\end{equation*}
$$

To prove this identity, we write

$$
\begin{aligned}
\sum_{j, k=0}^{m} \frac{\left(c_{j}+c_{k}\right)^{2}}{s_{j}^{2} s_{k}^{2}} & =\sum_{j, k=0}^{m} \frac{c_{j}^{2}+c_{k}^{2}}{s_{j}^{2} s_{k}^{2}} \quad\left(\text { as } c_{m-j}=-c_{j} \text { and } s_{m-j}=s_{j}\right) \\
& =2\left(\sum_{j=0}^{m} \frac{c_{j}^{2}}{s_{j}^{2}}\right)\left(\sum_{k=0}^{m} \frac{1}{s_{k}^{2}}\right) \\
& =2\left(\sum_{j=0}^{m} \frac{c_{j}^{2}}{s_{j}^{2}}\right) \sum_{k=0}^{m}\left(1+\frac{c_{k}^{2}}{s_{k}^{2}}\right)
\end{aligned}
$$

and complete the proof thanks to 17 .
To obtain the expression (4) of $\mathrm{I}_{m}(t)$, we write

$$
\begin{aligned}
\sum_{j, k=0}^{m} \frac{\left(c_{j}+c_{k}\right)^{2}}{s_{j}^{2} s_{k}^{2}} \frac{1}{1-t x_{j k}} & =\frac{1}{2} \sum_{j, k=0}^{m}\left(\frac{c_{j}+c_{k}}{\left(1-c_{j}\right)\left(1-c_{k}\right)}-\frac{c_{j}+c_{k}}{\left(1+c_{j}\right)\left(1+c_{k}\right)}\right) \frac{1}{1-t x_{j k}} \\
& =\sum_{j, k=0}^{m} \frac{c_{j}+c_{k}}{\left(1-c_{j}\right)\left(1-c_{k}\right)} \frac{1}{1-t x_{j k}}
\end{aligned}
$$

The latter identity follows from replacing $j$ by $m-j$ and $k$ by $m-k$.
Let us now extract the coefficient of $t^{0}$ in (4). This gives

$$
\begin{equation*}
0=\frac{m(m+1)}{4}-\frac{1}{8(m+1)^{2}} \sum_{j, k=0}^{m} \frac{c_{j}+c_{k}}{\left(1-c_{j}\right)\left(1-c_{k}\right)}, \tag{19}
\end{equation*}
$$

and the expression (5) of $\mathrm{I}_{m}(t)$ follows.

## 3 Small times: linear and before

When $m$ is fixed and $n \rightarrow \infty$, the asymptotic behaviour of the numbers $I_{m, n}$ is easily derived from Theorem 1 as sketched just after the statement of this theorem. For $m \geq 3$,

$$
I_{m, n}=\frac{m(m+1)}{4}+O\left(x_{00}^{n}\right)
$$

where $x_{00}=1-\frac{4}{m} \sin ^{2} \frac{\pi}{2 m+2}$.
In this section and the next two ones, we consider the case where $n \equiv n_{m}$ depends on $m$, and $m \rightarrow \infty$. As in [4], three main regimes appear: linear $\left(n_{m}=\Theta(m)\right)$ ), cubic ( $n_{m}=\Theta\left(m^{3}\right)$ ) and intermediate ( $m \ll n_{m} \ll m^{3}$ ). This can be partly explained using the following simple bounds.

Lemma 10 For $m \geq 3$ and $n \geq 0$, there holds

$$
\frac{m(m+1)}{4}\left(1-x_{00}^{n}\right) \leq \mathbf{I}_{m, n} \leq \frac{m(m+1)}{4}-\frac{c_{0}^{2}}{2(m+1)^{2} s_{0}^{4}} x_{00}^{n}
$$

In particular, if $n \equiv n_{m}$ and $m \rightarrow \infty$,

$$
\mathrm{I}_{m, n}=\frac{m(m+1)}{4}-\Theta\left(m^{2} x_{00}^{n}\right)
$$

Proof: These inequalities follow from the expression of $I_{m, n}$ given in Theorem 1 The upper bound is obtained by retaining only, in the sum over $j$ and $k$, the term obtained for $j=k=0$. The lower bound follows from $\left|x_{j k}\right| \leq x_{00}$ and (18). $\square$ Observe that $x_{00}=1-O\left(1 / m^{3}\right)$. The lower bound on
$\mathrm{I}_{m, n}$ already shows that if $n \gg m^{3}$, then $x_{00}{ }^{n}=o(1)$ and $\mathrm{I}_{m, n} \sim \frac{m(m+1)}{4}$. Also, if $n \sim \kappa m^{3}$ for some $\kappa>0$, then $x_{00}{ }^{n} \sim \alpha$ for some $\alpha \in(0,1)$ : then $\mathrm{I}_{m, n}$ is still quadratic in $m$, but the upper bound shows that the ratio $I_{m, n} / m^{2}$ will be less than $1 / 4$. The other regimes correspond to cases where $n \ll m^{3}$.

This section is devoted to the linear (and sub-linear) regime. We first state our results, and then comment on their meaning.
Proposition 11 Assume $n \equiv n_{m}=o(m)$. Then

$$
\frac{\mathrm{I}_{m, n}}{n}=1+O(n / m)
$$

Assume $n \equiv n_{m}=\Theta(m)$. That is, $\kappa_{1} m \leq n_{m} \leq \kappa_{2} m$ for two positive constants $\kappa_{1}$ and $\kappa_{2}$. Then

$$
\frac{\mathrm{I}_{m, n}}{n}=f(n / m)+O(1 / m)
$$

where

$$
\begin{aligned}
f(\kappa) & =\frac{1}{2 \pi \kappa} \int_{0}^{\infty} \frac{1-\exp \left(-8 \kappa t^{2} /\left(1+t^{2}\right)\right)}{t^{2}\left(1+t^{2}\right)} d t \\
& =\sum_{j \geq 0}(-1)^{j} \frac{(2 j)!}{j!(j+1)!^{2}}(2 \kappa)^{j} .
\end{aligned}
$$

Comment. When $n_{m}$ is sub-linear, the inversion number equals its largest possible value, $n$, with high probability. For instance, $\mathrm{I}_{1000,10} \simeq 9.9$. When $n_{m}$ grows linearly with $m$, the expected inversion number is still linear in $n$, but with a ratio $f(\kappa)$, where $\kappa=n / m$. This ratio decreases from $f(0)=1$ to $f(\infty)=0$ as $\kappa$ increases from 0 to $\infty$. The fact that $f(0)=1$ is consistent with the sub-linear result.

Note that for a related continuous time chain, with inversion number $D_{m}^{t}$, it has been proved that when $t=\kappa m$, the random variable $D_{m}^{t} / t$ converges in probability to a function of $t$ described in probabilistic terms [4].

Proof: The starting point of both results is the following expression of $I_{m, n}$, which corresponds to (5):

$$
\begin{equation*}
\mathrm{I}_{m, n}=\frac{1}{8(m+1)^{2}} \sum_{k, j=0}^{m} \frac{c_{j}+c_{k}}{\left(1-c_{j}\right)\left(1-c_{k}\right)}\left(1-\left(1-\frac{4}{m}\left(1-c_{j} c_{k}\right)\right)^{n}\right) \tag{20}
\end{equation*}
$$

- Assume $n_{m}=o(m)$. Then

$$
\left(1-\frac{4}{m}\left(1-c_{j} c_{k}\right)\right)^{n}=1-\frac{4 n}{m}\left(1-c_{j} c_{k}\right)+\left(1-c_{j} c_{k}\right)^{2} O\left(\frac{n^{2}}{m^{2}}\right)
$$

uniformly in $j$ and $k$. Thus

$$
\mathrm{I}_{m, n}=\frac{n}{2 m(m+1)^{2}} \sum_{k, j=0}^{m} \frac{\left(c_{j}+c_{k}\right)\left(1-c_{j} c_{k}\right)}{\left(1-c_{j}\right)\left(1-c_{k}\right)}+\frac{1}{4(m+1)^{2}} \sum_{k, j=0}^{m} \frac{\left(1-c_{j} c_{k}\right)^{2}}{\left(1-c_{j}\right)\left(1-c_{k}\right)} O\left(\frac{n^{2}}{m^{2}}\right)
$$

(we have bounded $\left|c_{j}+c_{k}\right|$ by 2 ) and the result follows using

$$
\sum_{k, j=0}^{m} \frac{\left(c_{j}+c_{k}\right)\left(1-c_{j} c_{k}\right)}{\left(1-c_{j}\right)\left(1-c_{k}\right)}=2 m(m+1)^{2}
$$

and

$$
\begin{equation*}
\sum_{k, j=0}^{m} \frac{\left(1-c_{j} c_{k}\right)^{2}}{\left(1-c_{j}\right)\left(1-c_{k}\right)}=(2 m+1)(m+1)^{2} \tag{21}
\end{equation*}
$$

To prove these two identities, one may start from the following "basic" identity:

$$
\begin{equation*}
\sum_{j=0}^{m} \frac{1}{1-c_{j}}=(m+1)^{2} \tag{22}
\end{equation*}
$$

which follows for instance from 19 .

- Assume now $n_{m}=\Theta(m)$ and denote $\kappa=n / m$. Then

$$
\left(1-\frac{4}{m}\left(1-c_{j} c_{k}\right)\right)^{n}=\exp \left(-4 \kappa\left(1-c_{j} c_{k}\right)\right)\left(1+\left(1-c_{j} c_{k}\right)^{2} O\left(n / m^{2}\right)\right)
$$

Thus

$$
\begin{aligned}
\mathrm{I}_{m, n}=\frac{1}{8(m+1)^{2}} \sum_{k, j=0}^{m} & \frac{c_{j}+c_{k}}{\left(1-c_{j}\right)\left(1-c_{k}\right)}\left(1-\exp \left(-4 \kappa\left(1-c_{j} c_{k}\right)\right)\right) \\
& +\frac{1}{8(m+1)^{2}} \sum_{k, j=0}^{m} \frac{\left(c_{j}+c_{k}\right)\left(1-c_{j} c_{k}\right)^{2}}{\left(1-c_{j}\right)\left(1-c_{k}\right)} \exp \left(-4 \kappa\left(1-c_{j} c_{k}\right)\right) O\left(n / m^{2}\right)
\end{aligned}
$$

By (21), the absolute value of the second term above is bounded by

$$
\frac{1}{4(m+1)^{2}} \sum_{k, j=0}^{m} \frac{\left(1-c_{j} c_{k}\right)^{2}}{\left(1-c_{j}\right)\left(1-c_{k}\right)} O\left(n / m^{2}\right)=O(n / m)=O(1)
$$

Recall that $c_{j}=\cos \frac{(2 j+1) \pi}{2 m+2}$. Hence the first term in the expression of $\mathrm{I}_{m, n}$ looks very much like a (double) Riemann sum, but one must be careful, as the integral

$$
\int_{0}^{\pi} \int_{0}^{\pi} \frac{\cos x+\cos y}{(1-\cos x)(1-\cos y)}(1-\exp (-4 \kappa(1-\cos x \cos y))) d x d y
$$

diverges (the integrand behaves like $1 / x$ around $x=0$, and like $1 / y$ around $y=0$ ). Let us thus write

$$
\begin{aligned}
1-\exp \left(-4 \kappa\left(1-c_{j} c_{k}\right)\right) & =\left[1-\exp \left(-4 \kappa\left(1-c_{j}\right)\right)\right]+\left[1-\exp \left(-4 \kappa\left(1-c_{k}\right)\right)\right] \\
- & {\left[1-\exp \left(-4 \kappa\left(1-c_{j}\right)\right)-\exp \left(-4 \kappa\left(1-c_{k}\right)\right)+\exp \left(-4 \kappa\left(1-c_{j} c_{k}\right)\right)\right] }
\end{aligned}
$$

so that

$$
\mathbf{I}_{m, n}=2 S_{1}-S_{2}+O(1)
$$

with

$$
S_{1}=\frac{1}{8(m+1)^{2}} \sum_{k, j=0}^{m} \frac{c_{j}+c_{k}}{\left(1-c_{j}\right)\left(1-c_{k}\right)}\left(1-\exp \left(-4 \kappa\left(1-c_{j}\right)\right)\right)
$$

and

$$
\begin{aligned}
S_{2}=\frac{1}{8(m+1)^{2}} \sum_{k, j=0}^{m} & \frac{c_{j}+c_{k}}{\left(1-c_{j}\right)\left(1-c_{k}\right)} \\
& \times\left[1-\exp \left(-4 \kappa\left(1-c_{j}\right)\right)-\exp \left(-4 \kappa\left(1-c_{k}\right)\right)+\exp \left(-4 \kappa\left(1-c_{j} c_{k}\right)\right)\right]
\end{aligned}
$$

The first sum reads

$$
\begin{aligned}
S_{1} & =\frac{1}{8(m+1)^{2}} \sum_{j=0}^{m} \frac{1-\exp \left(-4 \kappa\left(1-c_{j}\right)\right)}{1-c_{j}} \sum_{k=0}^{m} \frac{c_{j}+c_{k}}{1-c_{k}} \\
& =\frac{1}{8} \sum_{j=0}^{m} \frac{1-\exp \left(-4 \kappa\left(1-c_{j}\right)\right)}{1-c_{j}}\left(1+c_{j}\right)-\frac{1}{8(m+1)} \sum_{j=0}^{m} \frac{1-\exp \left(-4 \kappa\left(1-c_{j}\right)\right)}{1-c_{j}}
\end{aligned}
$$

as

$$
\sum_{k=0}^{m} \frac{1}{1-c_{k}}=(m+1)^{2} \quad \text { and } \quad \sum_{k=0}^{m} \frac{c_{k}}{1-c_{k}}=m(m+1)
$$

(see (22)). Both terms in $S_{1}$ are now bona fide Riemann sums. More precisely,

$$
\frac{\pi}{m+1} \sum_{j=0}^{m} \frac{1-\exp \left(-4 \kappa\left(1-c_{j}\right)\right)}{1-c_{j}}\left(1+c_{j}\right)=\int_{0}^{\pi} \frac{1-\exp (-4 \kappa(1-\cos x))}{1-\cos x}(1+\cos x) d x+O(1 / m)
$$

uniformly in $\kappa \in\left[\kappa_{1}, \kappa_{2}\right]$, and similarly

$$
\frac{1}{m+1} \sum_{j=0}^{m} \frac{1-\exp \left(-4 \kappa\left(1-c_{j}\right)\right)}{1-c_{j}}=O(1)
$$

Thus

$$
S_{1}=\frac{m}{8 \pi} \int_{0}^{\pi} \frac{1-\exp (-4 \kappa(1-\cos x))}{1-\cos x}(1+\cos x) d x+O(1)
$$

Similarly, $S_{2}$ is a (double) Riemann sum associated with a converging integral, and is $O(1)$. Thus

$$
\mathrm{I}_{m, n}=2 S_{1}+O(1)=\frac{n}{4 \pi \kappa} \int_{0}^{\pi} \frac{1-\exp (-4 \kappa(1-\cos x))}{1-\cos x}(1+\cos x) d x+O(1)
$$

The integral can be rewritten by setting $t=\tan (x / 2)$, and this gives the second result of the proposition, with the integral expression of $f(\kappa)$. The expansion of $f(\kappa)$ in $\kappa$ is then routine.

## 4 Large times: cubic and beyond

Proposition 12 If $n \equiv n_{m} \gg m^{3}$, then

$$
\frac{\mathrm{I}_{m, n}}{m^{2}} \rightarrow \frac{1}{4}
$$

Assume $n \equiv n_{m}=\Theta\left(m^{3}\right)$. That is, $\kappa_{1} m^{3} \leq n_{m} \leq \kappa_{2} m^{3}$ for two positive constants $\kappa_{1}$ and $\kappa_{2}$. Then

$$
\frac{\mathrm{I}_{m, n}}{m^{2}} \sim g\left(n / m^{3}\right)
$$

where

$$
g(\kappa)=\frac{1}{4}-\frac{16}{\pi^{4}}\left(\sum_{j \geq 0} \frac{e^{-\kappa \pi^{2}(2 j+1)^{2} / 2}}{(2 j+1)^{2}}\right)^{2}
$$

Comment. When $n \gg m^{3}$, the inversion number equals, at least at first order, its "limit" value $\frac{m(m+1)}{4}$, which is the average number of inversions in a permutation of $\mathfrak{S}_{m+1}$ taken uniformly at random. When $n=\Theta\left(m^{3}\right)$, the inversion number is still quadratic in $m$, but with a ratio $g(\kappa)$, where $\kappa=n / m^{3}$. This ratio increases from 0 to $1 / 4$ as $\kappa$ goes from 0 to $\infty$, which makes this result consistent with the supercubic regime. Note that for a related continuous time chain, with inversion number $D_{m}^{t}$, it has been proved that when $t=\kappa m^{3}$, the random variable $D_{m}^{t} / m^{2}$ converges in probability to a function of $t$ described in probabilistic terms [4].

As said above, $\mathrm{I}_{m, n} \sim m^{2} / 4$ as soon as $n \gg m^{3}$. Whether the next term in the expansion of $\mathrm{I}_{m, n}$ is exact, that is, equal to $m / 4$, depends on how $n$ compares to $m^{3} \log m$, as shown by the following proposition. In particular, it clarifies when $\mathrm{I}_{m, n}=\frac{m(m+1)}{4}+o(m)$ : this happens beyond $n \sim 1 / \pi^{2} m^{3} \log m$.
Proposition 13 Let $c>0$, and $n \equiv n_{m} \sim c m^{3} \log m$. For all $\epsilon>0$,

$$
\frac{m(m+1)}{4}-O\left(m^{2+\epsilon-c \pi^{2}}\right)=\mathrm{I}_{m, n} \leq \frac{m(m+1)}{4}-\Theta\left(m^{2-\epsilon-c \pi^{2}}\right)
$$

Thus if $c<1 / \pi^{2}$, there exists $\gamma>0$ such that

$$
\mathrm{I}_{m, n} \leq \frac{m(m+1)}{4}-\Theta\left(m^{1+\gamma}\right)
$$

while if $c>1 / \pi^{2}$, there exists $\gamma>0$ such that

$$
\mathrm{I}_{m, n}=\frac{m(m+1)}{4}-O\left(m^{1-\gamma}\right)
$$

For the critical value $c=1 / \pi^{2}$, the following refined estimate holds: if $n \equiv n_{m} \sim 1 / \pi^{2} m^{3} \log m+$ $\alpha m^{3}+o\left(m^{3}\right)$, then

$$
\mathrm{I}_{m, n}=\frac{m(m+1)}{4}-\frac{16 m}{\pi^{4}} e^{-\alpha \pi^{2}}(1+o(1))
$$

Proof of Proposition 12: The first result is a direct consequence of Lemma 10, given that $x_{00}=1-$ $O\left(1 / m^{3}\right)$.
Assume now that $n_{m}=\Theta\left(m^{3}\right)$. We start from the following expression of $\mathrm{I}_{m, n}$, which corresponds to (4):

$$
\begin{equation*}
\mathrm{I}_{m, n}=\frac{m(m+1)}{4}-\frac{1}{8(m+1)^{2}} \sum_{k, j=0}^{m} \frac{c_{j}+c_{k}}{\left(1-c_{j}\right)\left(1-c_{k}\right)}\left(1-\frac{4}{m}\left(1-c_{j} c_{k}\right)\right)^{n} \tag{23}
\end{equation*}
$$

Let $M \equiv M_{m}$ be an integer sequence that tends to infinity in such a way $M_{m}=o(\sqrt{m})$. We split the sum over $j$ and $k$ into two parts: $j \leq M, k \leq M$ in the first part, $j>M$ or $k>M$ in the second part. Let us prove that the second part can be neglected. We have:

$$
\begin{aligned}
\left|\mathrm{SUM}_{2}\right| & :=\left|\sum_{j \text { or } k>M} \frac{c_{j}+c_{k}}{\left(1-c_{j}\right)\left(1-c_{k}\right)} x_{j k}{ }^{n}\right| \\
& \leq \sum_{j \text { or } k>M} \frac{2}{\left(1-c_{j}\right)\left(1-c_{k}\right)} \leq 4 \sum_{k=0}^{m} \frac{1}{1-c_{k}} \sum_{j=M+1}^{m} \frac{1}{1-c_{j}}
\end{aligned}
$$

By (22), the sum over $k$ is $O\left(m^{2}\right)$. Moreover, the sum over $j$ is a Riemann sum, and the function $x \mapsto 1 /(1-\cos x)$ is decreasing between 0 and $\pi$, so that

$$
\sum_{j=M+1}^{m} \frac{1}{1-c_{j}} \leq \frac{m+1}{\pi} \int_{\frac{(2 M+1) \pi}{2 m+2}}^{\pi} \frac{d x}{1-\cos x}=\frac{m+1}{\pi \tan \frac{(2 M+1) \pi}{4 m+4}}=O\left(\frac{m^{2}}{M}\right)
$$

This gives

$$
\mathrm{SUM}_{2}=O\left(\frac{m^{4}}{M}\right)=o\left(m^{4}\right)
$$

Let us now focus on small values of $j$ and $k$. The following estimates hold uniformly in $j$ and $k$, when
$0 \leq j, k \leq M$ :

$$
\begin{align*}
\frac{c_{j}+c_{k}}{\left(1-c_{j}\right)\left(1-c_{k}\right)} & =\frac{128(m+1)^{4}}{(2 j+1)^{2}(2 k+1)^{2} \pi^{4}}\left(1+O\left(\frac{M^{2}}{m^{2}}\right)\right)  \tag{24}\\
& =\frac{128 m^{4}}{(2 j+1)^{2}(2 k+1)^{2} \pi^{4}}(1+o(1)) \\
\left(1-\frac{4}{m}\left(1-c_{j} c_{k}\right)\right)^{n} & =\exp \left(-\frac{n \pi^{2}\left((2 j+1)^{2}+(2 k+1)^{2}\right)}{2 m(m+1)^{2}}\right)\left(1+O\left(n \frac{M^{4}}{m^{5}}\right)\right)  \tag{25}\\
& =\exp \left(-\frac{n \pi^{2}\left((2 j+1)^{2}+(2 k+1)^{2}\right)}{2 m^{3}}\right)(1+o(1))
\end{align*}
$$

We have used the fact that $n=O\left(m^{3}\right)$ and $M=o(\sqrt{m})$. Hence,

$$
\begin{aligned}
\mathrm{SUM}_{1} & :=\sum_{k, j=0}^{M} \frac{c_{j}+c_{k}}{\left(1-c_{j}\right)\left(1-c_{k}\right)} x_{j k}^{n} \\
& =\frac{128 m^{4}}{\pi^{4}}\left(\sum_{j=0}^{M} \frac{e^{-\frac{n \pi^{2}(2 j+1)^{2}}{2 m^{3}}}}{(2 j+1)^{2}}\right)^{2}(1+o(1)) .
\end{aligned}
$$

Finally, observe that

$$
\sum_{j=0}^{M} \frac{e^{-\frac{n \pi^{2}(2 j+1)^{2}}{2 m^{3}}}}{(2 j+1)^{2}}=h\left(\frac{n}{m^{3}}\right)+O\left(e^{-\frac{n M^{2}}{m^{3}}}\right)=h\left(\frac{n}{m^{3}}\right)(1+o(1))
$$

where

$$
h(\kappa)=\sum_{j=0}^{M} \frac{e^{-\kappa \pi^{2}(2 j+1)^{2} / 2}}{(2 j+1)^{2}} .
$$

Writing

$$
\mathrm{I}_{m, n}=\frac{m(m+1)}{4}-\frac{1}{8(m+1)^{2}}\left(\mathrm{SUM}_{1}+\mathrm{SUM}_{2}\right)
$$

then yields the result.
Proof of Proposition 13: The first result follows from the second identity of Lemma 10, using

$$
n=c m^{3} \log m(1+o(1)) \quad \text { and } \quad \log x_{00}=-\frac{\pi^{2}}{m^{3}}(1+O(1 / m))
$$

If $c<1 / \pi^{2}$, we choose $\epsilon$ such that $\gamma:=1-c \pi^{2}-\epsilon>0$, and the second result follows. If $c>1 / \pi^{2}$, we choose $\epsilon$ such that $\gamma:=c \pi^{2}-1-\epsilon>0$, and the third result follows.

Assume now $n=1 / \pi^{2} m^{3} \log m+\alpha m^{3}+o\left(m^{3}\right)$. We will show that the sum over $j$ and $k$ occurring in (23) is dominated by the contribution obtained for $j=k=0$. This contribution reads

$$
\frac{2 c_{0}}{\left(1-c_{0}\right)^{2}} x_{00}^{n}=\frac{128 m^{3}}{\pi^{4}} e^{-\alpha \pi^{2}}(1+o(1))
$$

The contribution obtained for $j=k=m$ is

$$
-\frac{2 c_{0}}{\left(1+c_{0}\right)^{2}} x_{00}^{n}=O(1 / m)
$$

Finally, for all other values of $j$ and $k$, there holds $0<x_{j k} \leq x_{01}$. Hence
$\left|\sum_{\substack{0 \leq k, j \leq m \\(k, j) \neq(0,0),(m, m)}} \frac{c_{j}+c_{k}}{\left(1-c_{j}\right)\left(1-c_{k}\right)} x_{j k}{ }^{n}\right| \leq 2 x_{01}{ }^{n} \sum_{0 \leq k, j \leq m} \frac{1}{\left(1-c_{j}\right)\left(1-c_{k}\right)}=2(m+1)^{4} x_{01}^{n}=O(1 / m)$.
We have first used the identity $(22)$, then $n=1 / \pi^{2} m^{3} \log m+\alpha m^{3}+o\left(m^{3}\right)$, and $\log x_{01}=-5 \pi^{2} / m^{3}(1+$ $o(1))$. The estimate of $\mathrm{I}_{m, n}$ follows.

## 5 The intermediate regime

Proposition 14 Assume $m \ll n_{m} \ll m^{3}$. Then, denoting $n \equiv n_{m}$,

$$
\frac{\mathrm{I}_{m, n}}{\sqrt{m n}} \rightarrow \sqrt{\frac{2}{\pi}}
$$

Comment. By Propositions 11 and 12 , one has

$$
\frac{\mathrm{I}_{m, n}}{\sqrt{m n}} \rightarrow \sqrt{\kappa} f(\kappa) \quad \text { if } \quad n_{m} \sim \kappa m
$$

while

$$
\frac{\mathrm{I}_{m, n}}{\sqrt{m n}} \rightarrow \frac{g(\kappa)}{\sqrt{\kappa}} \quad \text { if } \quad n_{m} \sim \kappa m^{3}
$$

It can be proved that

$$
\lim _{\kappa \rightarrow \infty} \sqrt{\kappa} f(\kappa)=\sqrt{\frac{2}{\pi}}=\lim _{\kappa \rightarrow 0} \frac{g(\kappa)}{\sqrt{\kappa}}
$$

which makes all three regimes consistent.
Note that for a related continuous time chain, with inversion number $D_{m}^{t}$, it has been proved that when $m \ll t \ll m^{3}$, the random variable $D_{m}^{t} / \sqrt{m t}$ converges in probability to $\sqrt{2 / \pi}$ [4].

Proof: The proof mixes arguments that we have already used for small and large times. As in the small time case, we start from 20. As in the large time case, we split the sum over $j$ and $k$ into two parts: $j \leq M, k \leq M$ in the first part, $j>M$ or $k>M$ in the second part. Here, $M=M_{m}$ is an integer sequence that satisfies

$$
\sqrt{\frac{m^{3}}{n}} \ll M \ll \min \left(\frac{m^{3}}{n}, m\left(\frac{m}{n}\right)^{1 / 4}\right)
$$

Such a sequence exists under the assumptions we have made on $n$.

We begin by bounding the second part. As in the large time case, one easily obtains

$$
\begin{align*}
\left|\mathrm{SUM}_{2}\right| & :=\left|\sum_{j \text { or } k>M} \frac{c_{j}+c_{k}}{\left(1-c_{j}\right)\left(1-c_{k}\right)}\left(1-x_{j k}^{n}\right)\right| \\
& \leq \sum_{j \text { or } k>M} \frac{2}{\left(1-c_{j}\right)\left(1-c_{k}\right)}=O\left(\frac{m^{4}}{M}\right) . \tag{26}
\end{align*}
$$

We now focus on the case $j, k \leq M$. The estimates and and hall uniformly in $j$ and $k$. This gives

$$
\begin{aligned}
\mathrm{SUM}_{1} & :=\sum_{k, j=0}^{M} \frac{c_{j}+c_{k}}{\left(1-c_{j}\right)\left(1-c_{k}\right)}\left(1-x_{j k}^{n}\right) \\
& =\frac{128 m^{4}}{\pi^{4}} \sum_{j, k=0}^{M} \frac{1-\exp \left(-\frac{n \pi^{2}\left((2 j+1)^{2}+(2 k+1)^{2}\right)}{2 m^{3}}\right)}{(2 j+1)^{2}(2 k+1)^{2}}(1+o(1))
\end{aligned}
$$

Using

$$
1-e^{a+b}=\left(1-e^{a}\right)+\left(1-e^{b}\right)-\left(1-e^{a}\right)\left(1-e^{b}\right)
$$

this may be rewritten as

$$
\begin{equation*}
\mathrm{SUM}_{1}=\frac{128 m^{4}}{\pi^{4}}\left(2 S_{M} \sum_{k=0}^{M} \frac{1}{(2 k+1)^{2}}-S_{M}^{2}\right)(1+o(1)) \tag{27}
\end{equation*}
$$

with

$$
S_{M}=\sum_{j=0}^{M} \frac{1-\exp \left(-\frac{n \pi^{2}(2 j+1)^{2}}{2 m^{3}}\right)}{(2 j+1)^{2}}
$$

The sum $S_{M}$ is close to a Riemann sum. More precisely,

$$
\begin{aligned}
S_{M} & =\frac{\pi \sqrt{n / m^{3}}}{2 \sqrt{2}} \int_{0}^{\sqrt{2} \pi M \sqrt{n / m^{3}}} \frac{1-e^{-x^{2}}}{x^{2}} d x(1+o(1)) \\
& =\frac{\pi^{3 / 2} \sqrt{n / m^{3}}}{2 \sqrt{2}}(1+o(1))
\end{aligned}
$$

as

$$
\int_{0}^{\sqrt{2} \pi M \sqrt{n / m^{3}}} \frac{1-e^{-x^{2}}}{x^{2}} d x=\int_{0}^{\infty} \frac{1-e^{-x^{2}}}{x^{2}} d x(1+o(1))=\sqrt{\pi}+o(1)
$$

In particular, $S_{M}=o(1)$. Returning to 27, let us finally note that

$$
\sum_{k=0}^{M} \frac{1}{(2 k+1)^{2}}=\frac{\pi^{2}}{8}(1+o(1))
$$

This gives

$$
\mathrm{SUM}_{1}=\frac{16}{\sqrt{2 \pi}} m^{2} \sqrt{m n}(1+o(1))
$$

Now recall that

$$
\mathrm{I}_{m, n}=\frac{1}{8(m+1)^{2}}\left(\mathrm{SUM}_{1}+\mathrm{SUM}_{2}\right)
$$

Combining the above estimate of $\mathrm{SUM}_{1}$ and the bound 26 on $\mathrm{SUM}_{2}$ gives the announced estimate of $\mathrm{I}_{m, n}$.

## 6 Perspectives

Many interesting Markov chains on groups have been studied, and it is natural to ask to which similar problems the approach used in this note could be adapted. To make this question more precise, let us underline that such problems may involve changing the dynamics of the chain, changing the statistics under consideration, or changing the underlying group.

Changing the chain. Already in the symmetric group $\mathfrak{S}_{m+1}$, a number of different dynamics have been considered. One can for instance multiply at each step by any transposition [3, 15, 28], or consider cyclic permutations by allowing multiplications by the transpositions $(0,1),(1,2), \ldots,(m-1, m)$ and $(m, 0)$, or only allow transpositions with the largest element [22, 14], or perform block transpositions [6], or shuffle the elements in various ways [2], etc. See for instance [12].

Changing the statistics. We have focused in this paper on the inversion number. It is an interesting parameter from a probabilistic point of view, as it gives an indication of whether the chain may be mixed at time $n$ or not. However, in certain biological contexts, it may be more sensible to estimate instead the natural "distance" between $\pi^{(0)}$ and $\pi^{(n)}$, defined as the minimum number of chain steps that lead from one to the other [3, 4]. For the chain studied here, this coincides with the inversion number, but for other dynamics it will be a different parameter. For instance, if we multiply by any transposition, one step suffices to go from 012 to 210 , whereas the inversion number of 210 is 3 . Clearly, the approach we have used here relies heavily on the possibility of describing in simple terms the evolution of the parameter under consideration (as we did by the combination of (6) and Lemma 3). Note that an explicit expression for the expected distance after $n$ (non-necessarily adjacent) transpositions has been given in [19].

Changing the group. Although many different chains in many different groups have been considered, we are primarily thinking of classical families of (finite or affine) Coxeter groups, because the inversion number admits in these groups a natural generalization (the length) which has usually a simple description [5], Chap. 8]. According to [18], an explicit formula, due to Troili, is already known for the average length of the product of $n$ generators in the affine group $\tilde{A}_{m}$. Another solved case is the hypercube $\mathbb{Z}_{2}^{m}$ [13].

Acknowledgements. The author thanks an anonymous referee, Niklas Eriksen and David Wilson for their suggestions, comments, and help with the bibliography.
